

Winter Storm Fern Situation Report*

Date of Preparation: June 2026

Jay Louissaint

Nikita Jayaprakash

Selina Carter

Disaster Manager Brief - Winter Storm Fern: Population Change and Community Impacts

Overview

1. Winter Storm Fern (January-February 2026) affected large portions of the southeastern U.S, producing snow, ice, transportation disruptions, power outages, and fatalities across multiple states.
2. Population change during the storm period was geographically concentrated in certain key counties rather than evenly distributed across the region.
 - a. The strongest positive changes in population (i.e. counties with a population *influx* throughout the 2 week aftermath) were repeatedly observed in a small number of counties, especially Perry County, Alabama and Cleburne County, Arkansas.
 - b. Negative changes (i.e. counties with an average *exodus* throughout the 2 week aftermath) were experienced most strongly in Sevier County, Tennessee.
 - c. Temporal results further suggest that the highest-change counties experienced sustained deviations from baseline, while average- and low-change counties generally stayed closer to zero with short-term fluctuations.
3. All counties do have a substantial drop in population change on February 9th, which we attribute to network outages.

*This report was prepared as part of the AI-SDM Fellowship at Carnegie Mellon University in collaboration with the Department of Statistics and Data Science.

Where Did Population Changes Occur?

Figure 1: Red shades represent counties where the population decreased relative to the baseline number (i.e., a population exodus), whereas blue shades represent population increases relative to baseline number (i.e., population influx). Population changes are measured relative to a baseline population level computed from the 45 days preceding the event. We can see there is little negative changes at these two dates.

The map highlights substantial variation in population change across affected counties. Some counties experienced large increases in observed population, while others experienced notable declines.

Takeaways (Figure 1)

- On February 2nd 3am EST, the counties with the most increased population are (Table 2):
 - Perry, Alabama (103.0%; baseline count ¹ = 19)
 - Cleburne, Arkansas (58.1%; baseline count = 29)
 - Hampton, South Carolina (57.4%; baseline count = 71)

¹Baseline count refers to the average number of Facebook Location Services-enabled users observed during the pre-event reference period. Values shown here have been rounded to the nearest integer. Additional details are provided in the Facebook Data Definitions section.

- On February 2nd 3am EST, the counties with the most decreased population are (Table 3):
 - Sevier, Tennessee (-22.8%; baseline count = 43598)
 - Carroll, Ohio (-22.7%; baseline count = 12)
 - Swain, North Carolina (-12.4%; baseline count = 3950)
- On February 12th 7pm EST, the counties with the most increased population are (Table 4):
 - Fairfield, South Carolina (31.3%; baseline count = 115)
 - Clay, West Virginia (26.2%; baseline count = 22)
 - Kemper, Mississippi (23.3%; baseline count = 651)
- On February 12th 7pm EST, the counties with the most decreased population are (Table 5):
 - Sevier, Tennessee (-21.7%; baseline count = 19924)
 - Alleghany, North Carolina (-14.7%; baseline count = 123)
 - Laurens, Georgia (-11.8%; baseline count = 35)

Counties Experiencing the Largest Changes

% Population Change Over Time: Highest-Change Counties

Figure 2: The figure shows that “highest change” includes both large increases and large decreases when counties are selected using largest absolute percent change in population. The time period is February 2nd to February 13th at 8hr intervals at 3am EST, 11am EST, and 7pm EST. Percent population change is relative to the baseline population (i.e., 45 days prior to the start of a disaster)

Counties with the greatest population changes generally experienced sustained departures from baseline conditions over multiple reporting periods. These counties did not simply experience a short-term spike or decline; many remained elevated or depressed for several days.

Takeaways (Figure 2)

- The time series makes clear that the largest changes are persistent over multiple days, not just one-day spikes, but each county has starkly different patterns of population change.
- Monroe has very strong positive population throughout this entire time period, which is at least double the population change rates of the other two counties.
- Fairfield maintains strong positive population change throughout this time period.
- Issaquena tends to have peaks around the 8am PST time, which is 10am local time.

Community Characteristics of Affected Counties

The demographic characteristics examined in this report reveal some potential relationships with population change, but no obvious overall patterns.

1. Counties experiencing the largest increases and decreases in population included both small and large communities, counties with relatively low and high median household incomes, and areas with widely varying poverty rates, age structures, and levels of vehicle access.
2. Some counties with substantial population influxes, such as Quitman County, Mississippi, had high poverty rates and relatively low incomes. Others, such as Osage County, Missouri, had much higher incomes and lower poverty rates.(Table 2)
3. Counties with the largest population declines generally exhibited high levels of vehicle access, but this pattern was not consistent enough to suggest a strong association.(Table 3)
4. No single demographic characteristic considered in this analysis appears to be a strong individual predictor of county-level population change during Winter Storm Fern. (Figure 7)
5. These findings suggest that the observed changes in population were likely influenced by a combination of local geographic, social, and disaster-specific factors rather than by any one demographic variable alone.

Comprehensive Situation Report

Formatted based on LA Fire [Situation Report](#)

Summary

A major American winter storm, often referred to as Winter Storm Fern, started on Friday, January 23, 2026 and continued through January 26, 2026. The storm brought heavy snow and freezing rain to several U.S. states, ranging from the southern plains to the East Coast. Several states experienced network outages and extremely cold temperatures. For example, temperatures in Lexington, Kentucky fell to -16 degrees Fahrenheit (including wind chill) ([Lexington Herald-Leader \(2026\)](#)). Emergency declarations were issued ² ([Congressional Research Service \(2026\)](#)). Power outages due to downed trees and ice occurred in Southern States, such as Texas, Louisiana, Mississippi, and Tennessee. From Maine to New Mexico, states experienced significant snowfall and sleet. As of January 29th, there were up to 115 fatalities across 20 states after this winter storm, and approximately 2.5 million customers experienced power outages across the country ([Kothari \(2026\)](#)). Verisk, who are catastrophe risk modelling specialists, estimated a total of \$4 billion in industry losses while 14 states could each exceed \$50 million in insured losses ([Evans \(2026\)](#)).

The following visualizations are developed based on Meta AI for Good's data through Facebook with a focus on Tennessee, Kentucky and surrounding states. The data covers population movement during the collection period of January 30 to February 12. These datasets use location activity from Facebook users to estimate how populations shift during a crisis. Data do not represent the entire population in the area. Counts of people within a certain region are recorded at 8-hour intervals in this dataset. The counts during the crisis are compared to the counts at a baseline, which are the counts in the same region 45 days prior to data collection. These regions are either Bing tiles, what are about 1.5 x 1.5 mile blocks, or administrative regions as determined by [GADM](#). These counts are aggregated to the county level for this analysis.

The main findings suggest that population change during the post-storm period was geographically concentrated rather than evenly distributed across the region. The strongest positive changes in population (i.e. counties with a population *influx* throughout the 2 week aftermath) were repeatedly observed in a small number of counties, especially Perry County, Alabama and Cleburne County, Arkansas. Meanwhile, negative changes (i.e. counties with an average *exodus* throughout the 2 week aftermath) were experienced most strongly in Sevier County, Tennessee. Temporal results further suggest that the highest-change counties experienced sustained deviations from baseline, while average- and low-change counties generally stayed closer

²Arkansas, Georgia, Indiana, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia.

to zero with short-term fluctuations. However, the average- and low-change counties do have a substantial drop in population change on February 9th.

How the Data Are Constructed

The Facebook data used in this report comes from Meta’s Data for Good crisis datasets. In plain terms, these datasets use location activity from Facebook users to estimate how population shifts during a crisis. The data does not represent everyone in the affected area: for population and movement datasets, it only represents Facebook app users who have Location Services enabled.

The data is constructed by comparing what is observed during the crisis period to what was typical before the crisis. Namely, population movements during the storm is compared to a pre-crisis baseline of 45-days prior to data collection. Because the data is relative to a baseline, the main signal is not the raw count itself, but whether a place is above or below its pre-crisis level.

Temporally, the population and movement datasets use fixed 8-hour windows. These windows begin at 00:00, 08:00, and 16:00 Pacific Time (PST). This means that the time periods do not automatically adjust to local time zones. For our analysis, we report time windows in Eastern Time (EST).

Some Meta crisis datasets are provided directly as Bing tile data, while others are provided as administrative-region data. **For the rest of this report, we use the Bing tile version as the primary aggregation source because Bing tiles are strictly defined grid cells with clear latitude and longitude coordinates, and they are more granular than administrative regions.** This makes the spatial assignment process more transparent and reproducible. In contrast, the administrative-region datasets are aggregated using boundaries provided to Meta by [GADM](#). Because we do not have direct access to the exact GADM polygons used by Meta for this aggregation, it is harder to verify or reproduce the administrative-region boundaries precisely.

When the data is provided as Bing tiles, each observation is tied to a grid cell with a latitude and longitude, which is defined as the polygon centroid point. We assign each Bing centroid point to the county that contains it. This allows the tile-level data to be summarized at the county level while preserving a clear record of how the geographic aggregation was performed.

For example, a Bing tile located inside Davidson County, Tennessee would be assigned the Davidson County name and GEOID. If many Bing tiles fall within Davidson County, their values can then be averaged, summed, or otherwise summarized to produce a county-level measure. This approach gives us a consistent way to move from tile-level observations to county-level reporting while relying on publicly available county boundary data. Note that all Bing tiles are smaller than counties in the data sets and hence all counties are accounted for in the merge.

Facebook Data Definitions

- **Baseline Population (n_{baseline}):** Average number of Facebook Location Services-enabled users present in a Bing tile during the baseline period prior to the event. Baseline values are calculated separately for each day of the week and 8-hour time window using historical observations before the start of data collection. Values below Meta’s privacy threshold are suppressed. Missing values are later imputed as part of the county-level analysis using the imputation procedure described in Section .
- **Crisis Population (n_{crisis}):** Number of Facebook Location Services-enabled users present in a Bing tile during a given 8-hour reporting window. To protect privacy, the counts are subject to noise addition, spatial smoothing, and suppression of small counts. Observations with counts below Meta’s reporting threshold may appear as missing values. Missing values are later imputed as part of the county-level analysis using the imputation procedure described in Section .
- **Population Change (%):** Percent change in Facebook Location Services-enabled user population counts per tile, calculated by dividing the difference by the baseline number (plus a small value, usually 1)
- **Time Windows:** aggregated over 3 fixed 8-hour time windows, beginning at 00:00, 08:00 and 16:00 PST, that represent changes in population
- **Bing Tiles:** Bing tiles divide the map into a grid of smaller spatial units. Each tile is identified by tile coordinates and a quadkey, which uniquely identifies a tile at a specific level of detail (Microsoft 2024). In the Meta crisis datasets used here, Bing tile level 14 is roughly 1.5 miles on each side near the equator.
- **Administrative Regions:** the polygon boundaries for administrative regions derived from the [Database of Global Administrative Areas](#), also known as GADM (GADM 2022). Note that we do not have access to these polygon shapes; hence we only use Bing tiles in this report.
- **Percent change:** Percent change in population counts of Facebook app users who have turned on the Location Services device setting on their mobile device and are along the vector defined by the starting Bing tile and ending Bing tile, calculated as the polygon movement at a given time window minus the baseline number (i.e., count 45 days prior to data collection period), divided by the baseline number.

Aggregation Choices

Bing tile observations are assigned to counties using the latitude and longitude coordinates of each tile centroid. The documentation defines these coordinates as the centers of the Bing tile grid cells. These centroid points are spatially joined to county polygons to assign county

names and GEOIDs. Quadkeys identify the original Bing tiles, but they are not used directly for county assignment in this report.

Imputation and County-Level Percent Change

For the county-level analysis, this report does not use the original tile-level `percent_change` field as the final county-level measure. Instead, the original `percent_change` column is preserved as `given_percent_change`, and a new county-level `percent_change` is calculated from the underlying baseline and crisis counts.

Some rows have missing values for `n_baseline` or `n_crisis` because of Meta’s privacy protections around small counts (counts less than or equal to 10 are not reported). To avoid dropping these rows entirely, missing `n_baseline` values are imputed as 3 and missing `n_crisis` values are imputed as 9. See Table 6 for percentage of data imputed.

After imputation, observations are summarized by county and reporting window. Because the data may include multiple observations within a single day, the reporting window is defined using both the date and the time-window information available in the data. For each county-window pair, the baseline counts are summed across all Bing tile observations in that county and reporting window, and the crisis counts are summed across those same observations. The county-window percent change is then calculated as:

$$\text{Percent Change}_{cw} = \frac{\sum_{i \in \text{Bing}_c} n_{\text{crisis}, ciw} - \sum_{i \in \text{Bing}_c} n_{\text{baseline}, ci}}{\sum_{i \in \text{Bing}_c} n_{\text{baseline}, ci} + 1} \times 100$$

where c is the county, w is the reporting window and Bing_c denotes the set of Bing tiles assigned to county c (based on centroid location). The small value added to the denominator follows the logic in the Meta documentation and prevents division by very small baseline values.

This means the maps and tables represent county-level population change based on aggregated counts.

The aggregation method depends on the type of variable being summarized. For count variables, such as `n_baseline` and `n_crisis`, summing is appropriate because the goal is to estimate the total observed Facebook users across tiles within a county. For relative variables, such as `given_percent_change`, or ratios, averaging can still be useful for descriptive comparisons, but these are not used as the main county-level percent change measure in this report.

For movement data, origin and destination counties are kept separate. Each row represents movement from one starting location to one ending location, so the analysis preserves both `start_county_geoid` and `end_county_geoid`. This avoids collapsing directional movement

into a single county and allows county-to-county movement patterns to be analyzed more accurately.

Outside Data Added

In addition to the Meta crisis datasets, county-level demographic data was added from the American Community Survey in 2022 ([U.S. Census Bureau \(2025\)](#)). This demographic data was incorporated with the use of the `tidycensus` package ([Walker and Herman \(2025\)](#)). This outside data provides context about the counties affected by the storm, including total population, median household income, poverty rate, share of residents age 65 and older, and share of households without vehicle access. These variables help interpret which communities may be more vulnerable during a crisis.

The demographic data is joined using GEOID, a standardized county identifier. This is important because county names alone are not unique across states. For example, many states have counties with the same name, but each county has a unique GEOID.

Limitations

These datasets should be interpreted as indicators of crisis-related change, not exact measures of the full population. The population and movement data only include Facebook users with Location Services enabled, so the sample may not represent all residents equally. Areas with fewer Facebook users or lower Location Services usage may be less reliable.

Privacy protections also affect interpretation. Small counts at the Bing tile level (less than 11 users) are removed, which can especially affect rural areas. For movement data, this means it is not reliable to calculate exact net flows by simply adding inbound and outbound movement, because some small movement vectors are excluded. To mitigate the effects of these missing values, this report employs a simple imputation procedure. The resulting imputations affect only about 0.6% of Bing tile observations and account for approximately 0.1–0.4% of total population counts in the selected reporting windows (see [Table 6](#)).

The baseline period is limited to the pre-crisis period available to Meta. This means the analysis does not have a long historical record of pre-crisis behavior. As a result, seasonal changes, holidays, or unusual pre-crisis conditions may affect the baseline. The data is useful for rapid situational awareness, but it should not be interpreted as a complete long-term population or economic dataset.

Finally, the data is time-limited. The documentation notes that some datasets are accessible for 90 days after the final update day and then discarded, which limits longer-term reproducibility and longitudinal analysis.

Movement

% Population Change

Figure 3: Red shades represent counties where the population decreased relative to the baseline number (i.e., a population exodus), whereas blue shades represent population increases relative to baseline number (i.e., population influx). Population changes are measured relative to a baseline population level computed from the 45 days preceding the event. We can see there is little negative changes at these two dates.

Takeaways (Figure 3)

- On February 2nd 12am PST, the counties with the most increased population are (Table 2):
 - Perry, Alabama (103.0%)
 - Cleburne, Arkansas (58.1%)
 - Hampton, South Carolina (57.4%)
- On February 2nd, the counties with the most decreased population are (Table 3):
 - Sevier, Tennessee (-22.8%)
 - Carroll, Ohio (-22.7%)

- Swain, North Carolina (-12.4%)
- On February 12th, the counties with the most increased population are (Table 4):
 - Fairfield, South Carolina (31.3%)
 - Clay, West Virginia (26.2%)
 - Kemper, Mississippi (23.3%)
- On February 12th, the counties with the most decreased population are (Table 5):
 - Sevier, Tennessee (-21.7%)
 - Alleghany, North Carolina (-14.7%)
 - Laurens, Georgia (-11.8%)

Time Series of Movement

The counties are grouped by percent population change over the recording period.³

% Population Change Over Time: Most Extreme-Change Counties

Figure 4: The figure shows that “highest change” includes both large increases and large decreases when counties are selected using largest absolute percent change in population. The time period is February 2nd to February 13th at 8hr intervals at 3am EST, 11am EST, and 7pm EST.

Takeaways (Figure 4)

- The time series makes clear that the largest changes are persistent over multiple days, not just one-day spikes, but each county has starkly different patterns of population change.
- Monroe county has very strong positive population change throughout this entire time period, which is at least double the population change rates of the other two counties.
- Fairfield county maintains strong positive population change throughout this time period.
- Issaquena tends to have peaks around the 11am EST time, which is 10am local time.

³See “Percent Change” in Facebook Data Definitions

% Population Change Over Time: Average-Change Counties

Figure 5: The figure shows that “average change” includes both large increases and large decreases when counties are selected using median absolute percent change in population. The three counties with average change have more variation in population change with both positive and negative changes.

Takeaways (Figure 5)

- These counties provide a useful comparison group for interpreting the more extreme counties.
- In comparison to the high-change counties, these three counties have their percentage population change constrained within $[-10\%, 10\%]$, indicating much lower rates of population change.
- All counties have a drop in population change at February 9th of similar magnitudes. Which could be due to a region-wide network outage affecting Facebook users.
- Fayette, Ohio and Ohio, Kentucky follow similar trends in variation, but Ohio, Kentucky has a noticeable spike on February 8th.
- Union county is the only county of these three that has negative population rates in this time periods.

% Population Change Over Time: Lowest-Change Counties

Figure 6: The figure shows that “lowest change” includes one large decrease when counties are selected using lowest absolute percent change in population. The three counties with the lowest change have a notable drop into extreme negative population change on February 9th.

Takeaways (Figure 6)

- These three counties follow a similar pattern with relatively stable populations around zero and a sharp drop at February 9th.
- These counties never have strong positive population change, implying that populations may have either entered before this time period or left after this time period, because the constant negative change indicates people leaving these counties.

Places

Takeaways (Table 1)

- The table is more useful as a data-quality warning than as a substantive movement analysis.
- Because movement vectors with small counts can be suppressed, these low-flow values should not be interpreted as exact zero movement.

Bottom 20 county-to-county crisis movement flows

Source: Bing Tiles

Starting County	Ending County	Total Crisis Movement
Carroll, Georgia	Fulton, Georgia	0
Fulton, Georgia	Sevier, Tennessee	0
Lafayette, Mississippi	Panola, Mississippi	0
Abbeville, South Carolina	Anderson, South Carolina	10
Adair, Kentucky	Russell, Kentucky	10
Arkansas, Arkansas	Prairie, Arkansas	10
Auglaize, Ohio	Shelby, Ohio	10
Barren, Kentucky	Warren, Kentucky	10
Bedford, Tennessee	Coffee, Tennessee	10
Blount, Tennessee	Sevier, Tennessee	10
Bolivar, Mississippi	Washington, Mississippi	10
Boone, Kentucky	Gallatin, Kentucky	10
Boyd, Kentucky	Cabell, West Virginia	10
Bradley, Tennessee	Polk, Tennessee	10
Brown, Illinois	Morgan, Illinois	10
Buncombe, North Carolina	McDowell, North Carolina	10
Burke, Georgia	Richmond, Georgia	10
Calloway, Kentucky	McCracken, Kentucky	10
Calloway, Kentucky	Vigo, Indiana	10
Campbell, Tennessee	Anderson, Tennessee	10

Table 1: The bottom 20 county-to-county crisis movement flows are all at zero or ten, likely due to data-collection thresholds for privacy concerns. Total crisis movement is the total (non-negative) number of people who have turned on the Location Services device setting on their mobile device for a given starting and ending county.

Counties with Most Increased Population on 2026-02-02 3am EST

Source: Bing Tiles

County	State	Population Change (%) ↓	Total Population	Median Household Income	Poverty Rate (%)	% Age 65+	% No Vehicle Access
Perry	Alabama	103.0%	8,031	\$37,654	31.4%	3.3%	8.0%
Cleburne	Arkansas	58.1%	25,226	\$55,798	13.9%	3.2%	5.3%
Hampton	South Carolina	57.4%	18,254	\$44,711	20.7%	2.2%	11.0%
Fairfield	South Carolina	53.2%	20,550	\$47,885	15.6%	3.2%	5.9%
Emanuel	Georgia	37.7%	23,026	\$52,772	25.7%	2.8%	8.2%
Orangeburg	South Carolina	37.6%	83,253	\$45,675	22.4%	3.1%	9.0%
Callaway	Missouri	28.1%	44,741	\$74,176	11.6%	2.2%	5.7%
Osage	Missouri	25.2%	13,402	\$76,681	8.6%	2.6%	5.6%
Chester	South Carolina	23.8%	32,182	\$52,458	18.7%	2.5%	6.3%
York	South Carolina	22.7%	293,673	\$89,095	8.4%	2.2%	3.7%
Sumter	Alabama	22.4%	11,878	\$33,310	26.5%	2.7%	9.5%
Kemper	Mississippi	18.9%	8,729	\$46,431	24.8%	3.1%	3.4%
Lincoln	Georgia	18.5%	7,854	\$56,907	17.0%	4.8%	7.1%
Quitman	Mississippi	18.2%	5,774	\$32,412	29.6%	2.4%	10.9%
Madison	Mississippi	17.9%	111,647	\$83,441	11.2%	2.2%	5.3%

Table 2: There are a few counties with high population change but low total population. All demographic information comes from the American Community Survey in 2022. County-level population change is calculated from aggregated baseline and crisis counts across all Bing tiles assigned to each county and reporting window.

Demographic Profile

Counties with Most Decreased Population on 2026-02-02 3am EST

Source: Bing Tiles

County	State	Population Change (%) ↑	Total Population	Median Household Income	Poverty Rate (%)	% Age 65+	% No Vehicle Access
Sevier	Tennessee	-22.8%	99,652	\$62,581	13.5%	2.7%	4.1%

Table 5: Similar to Feb 2nd, the counties with strong negative population change also have high levels of vehicular access. All demographic information comes from the American Community Survey in 2022. County-level population change is calculated from aggregated baseline and crisis counts across all Bing tiles assigned to each county and reporting window.

Demographic Correlations

Figure 7: There does not seem to be strong linear correlations between population change and the other demographic variables. Population change is the percent change in Facebook Location Services-enabled user population counts per Bing tile in each county at 8-hour intervals. All demographic variables are already at the county level from the American Community Survey in 2022. Days are the 1st to 10th day of data collection, from Feb 2nd to Feb 12. These counties are from 15 Southern states.

Imputation Summary

All available dates and hours

Count	Original Count (Users)	Total (New) Count (Users)	Imputed Count (Users)	Share of Total (New) Count Imputed	Total Bing Tiles	Number of Imputed Bing Tiles	Share of Bing Tiles Imputed
Baseline	341,681,836	342,000,436	318,600	0.1%	3,670,271	21,156	0.6%
Crisis	342,572,996	343,836,812	1,263,816	0.4%	3,670,271	21,990	0.6%

Table 6: Share of baseline and crisis Facebook user counts and Bing tile observations that originate from imputed values for the selected reporting window. Counts represent the number of Facebook users with Location Services enabled who were observed within a Bing tile during a reporting window. Because the data are reported repeatedly across multiple 8-hour reporting windows, the same user may contribute to counts in multiple observations. To preserve observations suppressed by Meta’s privacy protections (i.e., Excluding counts for Bing tiles with counts less than 11), missing baseline counts were imputed as 3 and missing crisis counts were imputed as 9. The table reports both the share of total counts and the share of Bing tile observations that were affected by this imputation procedure.
